## B10615056 黄暉翔

分工:加密

建置環境: python VScode

執行結果截圖:

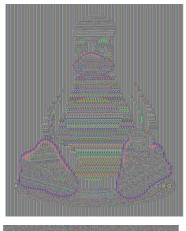

# 操作方式:

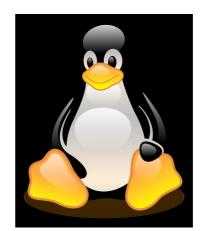

程式會開啟在同目錄下的photo.png,產生ppm檔,再經過三種MODE的加解密後產生相對應的ppm跟jpg檔。

# 執行結果圖:

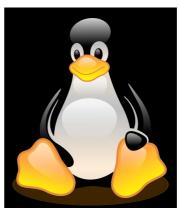

原圖:

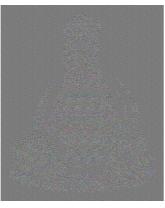

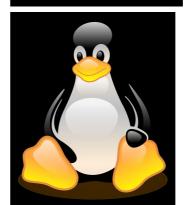

EBC:

CBC:

COOL:

#### 程式碼解說:

```
三種模式都先開PPM檔
f = open('EBC_encrypt.ppm','rb')
output = open('EBC_decrypt.ppm','wb')
開啟block
cipher_block = AES.new(key,AES.MODE_ECB)
讀取輸出前三行PPM的格式
    for i in range(3):
      data = f.readline()
      output.write(data)
      print(data)
持續讀取PPM檔直到EOF,每次讀取16bytes = 128bits = 1 block
    data = f.read(16)
    while data:
避免最後一個block不夠16bytes,後續補0直到16bytes
      if len(data) < 16:
       pd = 16 - len(data)
       for i in range (pd):
         data += bytes([0])
Cool:先說明我們第三個mode的作法,是將CBC中的IV向右roll 1 bit
    跟CBC一樣先進行跟IV XOR在加密
    temp = []
    for d,i in zip(data ,iv):
        temp.append((d ^ i) % 256)
    data = bytes(temp)
    cipher = cipher_block.encrypt(data)
 output.write(cipher)
    接著將IV向右roll 1 bit,並讀取下個block
 temp = iv[15:16]
 temp += iv[:15]
 iv = bytes(temp)
 data = f.read(16)
```

在每個mode最後,關檔並且將加解密後的ppm另存jpg以便檢視 f.close() output.close() jpgPicture = 'Cool\_encrypt.jpg' im = Image.open('Cool\_encrypt.ppm') im.save(jpgPicture)

## 遇到困難與心得:

python 在裝cypryto的時候花了一些時間,再來只要知道ppm的格式然後再按照相應的架構圖實作就沒什麼問題了。
